links

# What is a Graph?

- A **graph**  $G$  is an ordered pair of sets  $[V, E]$  where  
 $V = \{v_1, v_2, \dots, v_i, \dots, v_n\}$  is a set of **vertices** (i.e., nodes)  
 $E = \{e_1, e_2, \dots, e_i, \dots, e_m\}$  is a set of **edges** (i.e., links)
- Data structure heavily used in computing problems.

# What is a Graph?

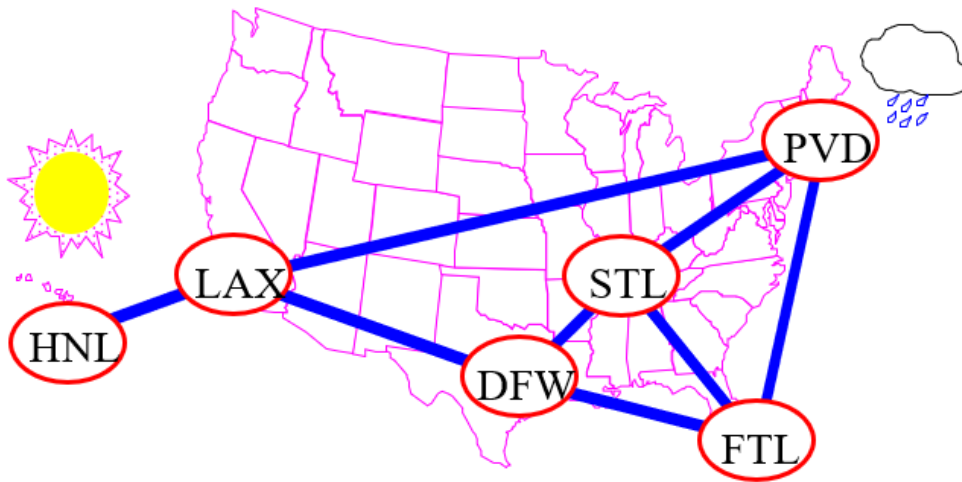

*Undirected Graph*

*Directed Graph (digraph)*

# Applications

- Networks:  
(roads, flights, communications)

*Undirected Graph*

*Flight  
Connections*

*Directed Graph (digraph)*

# What is a Graph?

- A graph  $G = (V, E)$  is composed of:
  - $V$ : set of **vertices** (i.e., *nodes*)
  - $E$ : set of **edges** (i.e., *links*) connecting the **vertices** in  $V$
- An **edge**  $e = (u, v)$  is a pair of **vertices**
- Example:

*Undirected Graph*

*Directed Graph (digraph)*

# Vertices

- $V$  represents the number of vertices in the graph
- $V(G)$  is a set of vertices or nodes which can represent an object that needs to be “connected”

# Edges

- a distinct pair of vertices
- indicates a valid/existing connection between two vertices
- $E \rightarrow$  the number of edges in the graph
- $E(G) \rightarrow$  a set consisting of a pair of vertices
- *an edge which connects the same vertex is called a loop*

# Types of Graphs

- Directed Graphs
- Undirected Graphs
- Weighed Graphs
- Trees

# Directed Graph or Digraph

- There is an order of the pair of vertices in the set of edges
- The connecting lines are usually represented with an arrow

# Undirected Graph

- The order of the vertices in the pair of vertices in the set of edges does not matter

# Weighted Graph

- Each edge has an associated weight which could indicate cost, distance, time, etc. between two adjacent vertices

# Tree

- A connected graph with no cycles

*Examples of a Tree*

# Adjacent Vertices

- if two vertices are joined by an edge they are said to be *adjacent*

*Adjacent Vertices:*

*A & C*

*A & B*

*B & C*

# Incident Vertices

- if an edge connects two vertices, the vertices are said to be *incident* to the edge

*A is incident to edge AC*  
*B is incident to edge BA*

# Degree of a Vertex

- The degree of a vertex ***v*** is the number of vertices adjacent to it (or the number of edges incident to it)
- Represented as ***deg(v)*** or ***degree(v)***

# Paths

- Given a graph  $G$  which includes the vertices  $x$  and  $y$ .
- A path from  $x$  to  $y$  length  $k$  is a sequence of  $k$  distinct edges

$e_1, e_2, \dots, e_n$  such that:

$$e_1 = (x, x_1), e_2 = (x_1, x_2), \dots e_k = (x_{k-1}, y)$$

# Path

*Path from A to D: A-B-C-D*

*Path from B to E: B-A-C-D-E*

# Cycle

- If  $x$  and  $y$  are the same vertex, then we say that the path from  $x$  to  $y$  is a cycle

*Cycles:*  
*A-B-C-A*  
*C-B-A-C*

# Connectivity

- A graph  $G$  is connected if for every pair of vertices  $x$  and  $y$ , there exists a path from  $x$  to  $y$

Connected Graph

Disconnected Graph

# Distance

- The distance  $d(x,y)$  from  $x$  to  $y$  is the smallest number of edges in a path from  $x$  to  $y$

$$d(A,C) = 1$$

$$d(B,C) = 1$$

# Comparison

- The adjacency matrix is great for adjacency check  $O(1)$ ! (but slow on vertex add/removal).
- The adjacency list is great for sparse/few edge graphs (uses heap/pointers but does save space for edges that don't exist.) Also rather efficient to add and query, vertices.
